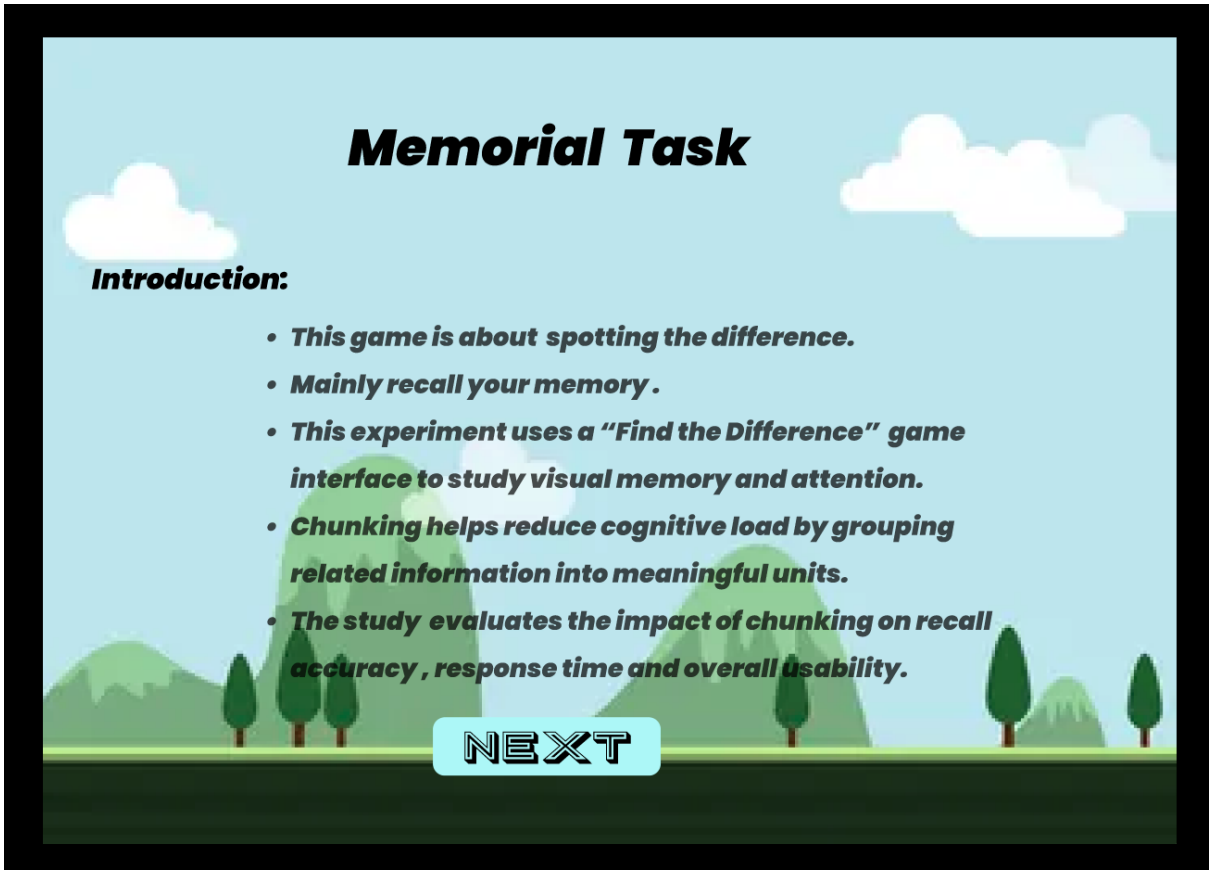
EX No 2:

Design a UI where users recall visual elements (e.g., icons or text chunks). Evaluate the effect of chunking on user memory.

Figma – How to Setting Up the UI

A. Home Screen (Introduction Page)

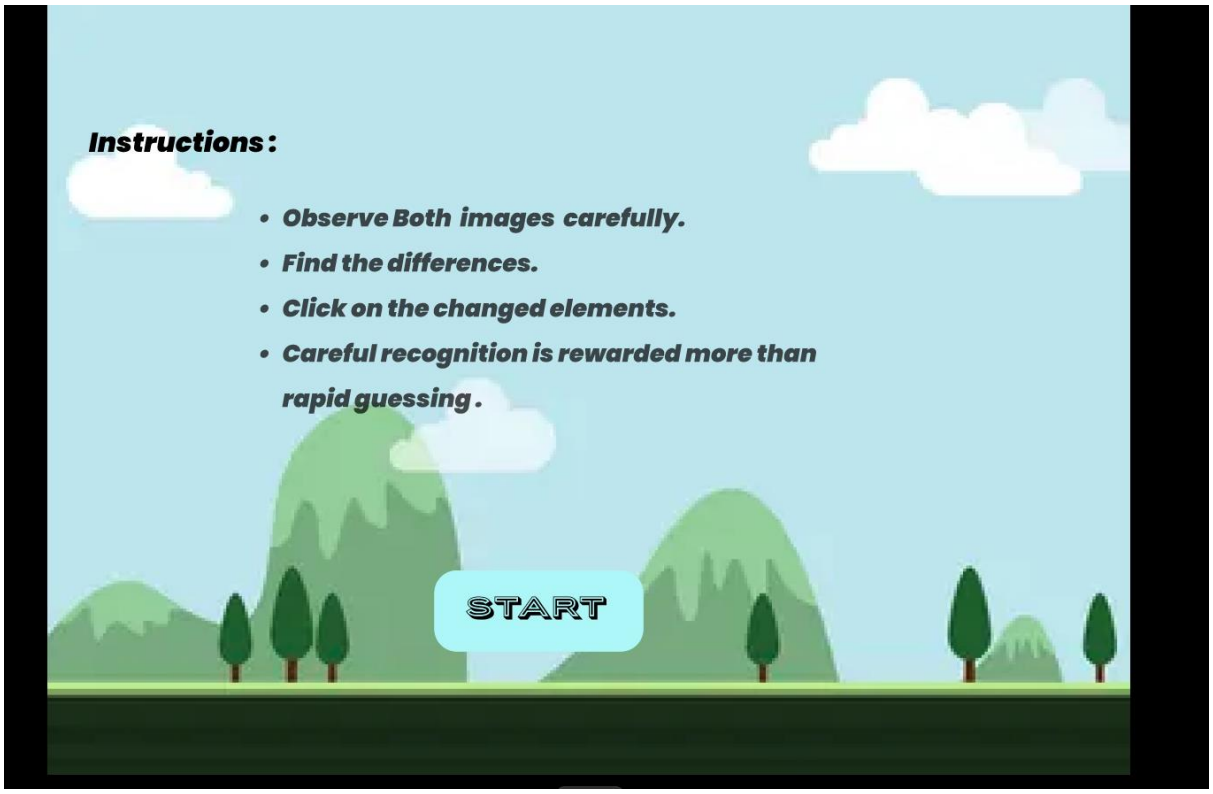
This screen introduces the user to the Memorial Task experiment. It explains that the task is based on a “Spot the Difference” game, where users must carefully observe visual elements and recall changes. The purpose of this experiment is to study visual memory, attention, and the effectiveness of chunking in improving recall performance. Chunking helps users group related visual information into meaningful units, reducing cognitive load and improving memory accuracy. A “Next” button is provided to guide the user to the instruction screen and begin the task.



B. Instruction Screen

This screen provides clear instructions to help users understand how to perform the task. Users are instructed to carefully observe both images and identify the differences between them. They must click on the elements that appear changed. The instructions emphasize that careful observation and recognition are more important than guessing quickly. This ensures

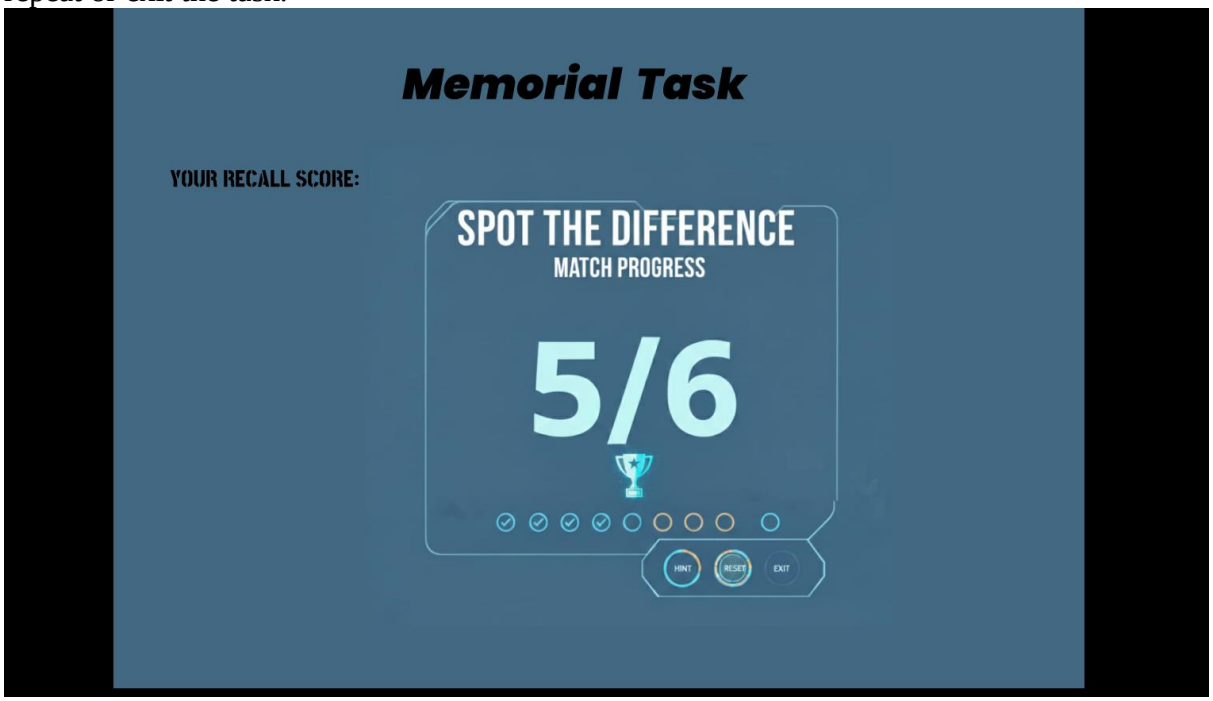
users focus on accuracy rather than speed. A “Start” button is provided to begin the actual memory task and move to the visual comparison phase.



C. Task Screen (Spot the Difference Phase)

This screen displays the visual scene where users perform the memory task. The interface presents a detailed image containing multiple objects such as toys, furniture, and decorations. Users must carefully observe the image and identify the elements that are different. A timer is included to measure the response time, which helps evaluate user performance and attention level. This phase tests the user’s visual memory, attention, and ability to recognize changes within grouped visual elements.

D. Result Screen (Recall Score / Feedback Screen)

This screen displays the user’s recall performance after completing the task. It shows the number of correctly identified differences in the form of a recall score (for example, 5/6). This feedback helps evaluate the user's visual memory accuracy and performance. The result screen allows researchers to analyze recall accuracy, response efficiency, and the impact of chunking on user memory. Additional options such as Hint, Reset, or Exit can be used to


repeat or exit the task.
